

```
#  
# Hey! Everything in here is better suited to httpd.conf, since  
# we get a performance boost if we can turn off AllowOverride and  
# not have to stat the webroot for every request. On the other  
# hand, this means we never have to touch apache once it's up.  
# Flexibility over performance.  
#  
# In an ideal world, you'd stick it in here on dev and your build  
# system would bundle the changes into (a file included in) httpd.conf  
# for your production deployment. Yeah. Do that.  
#  
# ETags are a bad idea if you have multiple web servers. We'll do  
# more explicit caching with Expires headers anyway.  
FileETag none  
  
# The base set of sensible PHP options. You could put these in your  
# php.ini file too, but having them in your Apache config puts  
# everything in one place. Magic quotes off because they are stupid.  
# Register globals off for the same reason. Track errors is so that  
# we can at least get at the error messages we hide using @func().  
# last_modified is a bad idea if we have any dynamic content. Short  
# tags make for a few saved bytes of cruft and are fine unless you're  
# running another XML preprocessor over your code (wtf?).
