

```
#
# Hey! Everything in here is better suited to httpd.conf, since
# we get a performance boost if we can turn off AllowOverride and
# not have to stat the webroot for every request. On the other
# hand, this means we never have to touch apache once it's up.
# Flexibility over performance.
#
# In an ideal world, you'd stick it in here on dev and your build
# system would bundle the changes into (a file included in) httpd.conf
# for your production deployment. Yeah. Do that.
#

# ETags are a bad idea if you have multiple web servers. We'll do
# more explicit caching with Expires headers anyway.
FileETag none

# The base set of sensible PHP options. These are a duplicate of those
# in www/php.ini.example, but I'm assuming your web host runs PHP as an Apache
# module and not as a CGI.
#
# If your Apache error log is full of barf like ...
#
# www/.htaccess: Invalid command 'php_value', perhaps misspelled or defined by a module
not included in the server configuration
#
# ... then PHP is a CGI. So comment out every php_value and php_flag command in this
# file and rename www/php.ini.example to www/php.ini and all should be happy again.
#
# Magic quotes off because they are stupid.
# Register globals off for the same reason.
# Track errors is so that we can at least get at the error messages we hide using @func().
# last_modified is a bad idea if we have any dynamic content.
# Short tags make for a few saved bytes of cruft and are fine unless you're
# running another XML preprocessor over your code (wtf?).
